Fig. 1. All categories in FractalDB-1k dataset. In the figure, we list 1,000 fractal categories which are rendered by Iterated Function Systems (IFS). Surprisingly, a CNN architecture classify the kind of image patterns with close to 100% in a training time.

2 Detailed categories in ImageNet-100 (IN100) and Places-30 datasets (P30)

Table 1 and 2 indicate detailed categories used in IN100 and P30, respectively. The both datasets are used in the main paper.

2 H. Kataoka et al.

3 Formula-driven Image Projections

3.1 Perlin Noise

Perlin Noise is a widely used method for generating textures in computer graphics. Just like Fractals, it is formula driven and is capable of constructing a database without human annotation. It matches the concept of *Pre-training without Natural Images*, and thus we implemented a PerlinDB in comparison to the FractalDB.

Generating Perlin Noise can be divided into three steps: definition of a 2Dgrid, calculation based on an argument point, and interpolation. First, a 2D-grid is defined with a random gradient vector given at each grid point. Next, the value of each argument point is computed by a dot product between gradient vectors at the four corners of the cell the point belongs to, and distance vectors between the argument point and the corresponding grid points. Finally, through an interpolation between the four values computed at step 2, the final value of the argument point is determined. Through this simple process, Perlin Noise can be generated.

The interval gradient vectors are defined affects the complexity of the generated noise. For example, compared to a noise computed from a grid with a gradient vector at every grid point, a noise computed from a grid with a gradient vector at every two grid points will be rougher in terms of complexity

3

Fig. 2. Example images of Perlin noise

Fig. 3. Example images of Bezier curve

of the noise. In the implementation of the PerlinDB, we used this difference in complexity to generate categories. For example, in the Perlin_100 dataset, we defined a 1024*1024 grid with gradient vectors2¹⁰⁻ⁿgrid points vertically and 2^{10-m} grid points horizontally (n, m = 1, 2, ..., 10), which makes category n_m. As a result, we managed to create 100 categories: 01_01, 01_02, ..., 10_09, 10_10. 01_01 is the category with the roughest noises, whereas 10_10 is the one with the most detailed noises.

As for the instances within each of the categories, we changed the gradient vectors. The angles that the gradient vectors are defined at each grid point are determined randomly. Therefore, redefining the gradient vectors would result in different gradient vectors, and thus a different noise. Using this simple method, Perlin_100cat is made of 10,000 instances per category.

Comparing several datasets, Perlin_100, Perlin_324, Perlin_1296, it seemed that the more categories there are, the better the accuracy is. Also, between datasets with the same number of categories but with different number of instances, datasets with more instances performed better. This tendency is the same as that of FractalDB.

4 H. Kataoka et al.

3.2 Bezier Curve

Just like PerlinDB, we also implemented a BezierCurveDB in comparison to the FractalDB. The BezierCurveDB consistes of images of Bezier Curve. It is a method for generating smooth curves in computer graphics. Bezier Curve is also formula driven and is capable of constructing a dataset without human annotation.

Bezier Curves is n-1-dimensional curves generated from n points. De Casteljau's algorithm is a widely used method for drawing the curves. Bezier Curves is generated by the following procedure:

- 1. Plot n dots
- 2. Form lines between thoes dots.
- 3. Plot dots dividing each of lines int to t: 1-t
- 4. Repeat (2) to (3) until only one dot is left

We implemented a BezierCurveDB for pre-training, and describe the dataset categories and instances. Note that generating images have a curve and lines formed to render the curves. The image categories is defined by a pair of n and s. The n is a number of dots plotting first in generating Bezier Curves. The s is a number of steps of dividing lines, in othe words, s is a number how many a line is divided epually. For example, in the Bezier_1024 dataset, we difined category n_s by combining 32 numbers (n,s = 3, 4, ..., 33, 34). As a result, we create 1024 categories: 03_03, 03_04, 03_05, ..., 34_32, 34_33, 34_34. 03_03 is the category of 2D curves generated with dividing lines into 3 equal parts. Next, as for the instances within each of the categories, we changed the place of first dots. By plotting dots randomly, BezierCurveDB is made of 1,000 instances per category.

We compared several datasets and BezierCurveDB (Bezier_144 and Bezier_1024) like PerlinDB. As a result, it found that BezierCurveDB has the same tendency as FractalDB and PerlinDB. The tendency is that the more the number of categories or instances, the higher the accuracy is.
